1 INTRODUCTION

KonSi – Malmquist Index software uses method of calculation Malmquist index is prepared in following papers:

Fare R, Grosskopf S, Lindgren B, Roos P. Productivity changes in Swedish pharmacies 1980-1989: A non-parametric Malmquist approach. J Prod Anal. 1992; 3(1-2): 85-101.

Fare R, Grosskopf S, Norris M, Zhang Z. Productivity Growth, Technical Progress, and Efficiency Change in Industrialized Countries. Am Econ Rev. 1994; 84(1): 66-83.

$$M^{t,t+1} = \underbrace{\frac{D^{t+1}(x^{t+1}, y^{t+1})}{D^t(x^t, y^t)}}_{\text{Efficiency change (EC)}} \times \underbrace{\left[\frac{D^t(x^{t+1}, y^{t+1})}{D^{t+1}(x^{t+1}, y^{t+1})} \frac{D^t(x^t, y^t)}{D^{t+1}(x^t, y^t)} \right]^{1/2}}_{\text{Technical change (TC)}}$$

$$\mathbf{M = EC * TC = PC * SC * TC}$$

M - malmquist index

EC - change in efficiency

TC - technical change

PC - Pure efficiency change

SC - scale efficiency change

2 METHODS OF MALMQUIST INDEX CALCULATION

KonSi – Malmquist Index software allows you to calculate Malmquist index using three calculation methods:

- Fixed base;
- Adjacent base;
- Seasonal calculation.

Fixed base Malmquist Index Method

Usage of the fixed-base calculation method assumes that you select one of researched time moments as a base moment. All further calculations are performed relative to this base moment. This calculation method is illustrated on Figure 1.

You calculate Fixed Malmquist Index values $MI(t_1, t_2)$ $MI(t_1, t_3)$... $MI(t_1, t_N)$

Figure 1 Fixed-base method of Malmquist index calculation

Adjacent-base Malmquist Index method

Usage of the adjacent-base calculation method assumes that each time moment is selected as the base moment and the moment next to base is considered as the analyzed time moment. This calculation method is illustrated on Figure 2.

Each moment is subsequently selected as the base moment
Moment next to the base is considered as the analyzed moment

Calculations are performed for the following time moment pairs:

t_1 and t_2
 t_2 and t_3
...
 t_{N-1} and t_N

You calculate Adjacent Malmquist Index values $MI(t_1, t_2)$ $MI(t_2, t_3)$... $MI(t_{N-1}, t_N)$

Figure 2 Adjacent-base method of Malmquist index calculation

Seasonal Malmquist Index method

Usage of the seasonal calculation method assumes that each of the moments is considered as the base moment and the analyzed moment is shifted to a given number of time moments ("season length") relative to the base. This calculation method is illustrated on Figure 3. In the example shown on this illustration, the season length parameter is set to 2.

Each moment is subsequently selected as a base
The analyzed moment is shifted
to a given number of moments ("season length")
relative to the base

Calculations are performed for the following time moment pairs

t_1 and t_3
 t_2 and t_4 (with season length equal to 2)
...
 t_{N-2} and t_N

You calculate Seasonal Malmquist Index values $MI(t_1, t_3)$ $MI(t_2, t_4)$... $MI(t_{N-2}, t_N)$

Figure 3 Seasonal method of Malmquist index calculation

Seasonal method is useful when it is necessary to calculate Malmquist index for periodical data (e.g. annual, quarterly, monthly data etc.). For example, if you are analyzing monthly data for many years and need to compare the same month in two years, you may use this method with season length set to 12 months. This allows you to compare January data in one year with January data in the other year, February data in one year with February data in the other year etc.

3 REPORTS ABOUT MALMQUIST INDEX VALUES

KonSi - Malmquist Index Software allows you to calculate Malmquist Index values, their components and CRS – VRS efficiencies used for calculation of indexes. The program generates five reports and saves them as .csv files. The reports are named in the following way:

- **Rpt1_MalmReportsDescription** – a report explaining terms or names used in other generated reports;
- **Rpt2_MI** – a report containing Malmquist index and its components computed for your dataset;
- **Rpt3_MalmEff** – a report containing DEA efficiencies computed during Malmquist index calculation;
- **Rpt4_DataForRegression** – a report containing data about Malmquist index, its components, DEA efficiencies computed during Malmquist index calculation and parameters of researched objects. This report may be used as source data for researching regression relationship between Malmquist Index and parameters of analyzed objects.
- **Rpt5_DataForPivotTable** – a report containing data about Malmquist index, its components, DEA efficiencies and object parameters. This report may be used as source data for creating table reports using MS Excel tools, for example, a pivot table.

3.1 Rpt1. Terms and names used in reports

This report is saved under the name **Rpt1_MalmReportsDescription**. The report allows you to get information about terms or names used in other generated reports. This report is generated as a .csv file which you may study using Microsoft Excel. The contents of this report are shown on Figure 4 - Figure 5.

	A	B	C	D	E	F	G	H	I	J	K	L
1	Rpt2_MI_AdjacentBase.csv	Report on Malmquist index components (calculation method: adjacent base time)

Figure 7 Rpt2_MI Report on Malmquist index and its components viewed in Notepad

The following elements are added to the report name depending on the Malmquist index calculation method:

- Method used for Malmquist index calculation, which was selected in the **Malmquist Index Calculation** window. This element may have one of the following values:
 - "FixedBase" which means that the Malmquist index and its components are computed using fixed-base method, i.e. one time moment is selected as a base time and the calculation is performed relative to that particular base time moment.
 - "Adjacent" which means that the Malmquist index and its components are computed using adjacent-base method, i.e. each moment is considered as a base moment and the moment next to the base is considered as the analyzed moment.
 - "Seasonal" which means that the Malmquist index and its components are computed using seasonal calculation method, i.e. each of the periods is used as a base time moment and the analyzed time moment is shifted to a given number of time moments relative to the base time moment.
- Method-specific options which are as follows:
 - "BasePeriod_Name" (for fixed-base calculation method) – an option indicating name of the time moment selected as a fixed base for computing Malmquist index
 - "ShiftValue_Value" (for seasonal calculation method) – an option indicating the number of time moments to which analyzed moments are shifted relative to base moments when "Seasonal" method is selected.

3.3 Rpt3. DEA efficiencies computed during Malmquist index calculation

This report is saved under the name **Rpt3_MalmEff**. The report allows you to get information about CRS and VRS efficiencies computed during Malmquist index calculation. This report is generated as a .csv file which you may study using Microsoft Excel. The contents of this report are shown on Figure 8 - Figure 9.

 - "Seasonal" which means that the Malmquist index and its components are computed using seasonal calculation method, i.e. each of the periods is used as a base time moment and the analyzed time moment is shifted to a given number of time moments relative to the base time moment.
- Method-specific options which are as follows:
 - "BasePeriod_Name" (for fixed-base calculation method) – an option indicating name of the time moment selected as a fixed base for computing Malmquist index
 - "ShiftValue_Value" (for seasonal calculation method) – an option indicating the number of time moments to which analyzed moments are shifted relative to base moments when "Seasonal" method is selected.

3.4 Rpt4. Terms and names used in reports

This report is saved under the name **Rpt4_DataForRegression**. This report contains data about Malmquist index, its components, DEA efficiencies computed during Malmquist index calculation and parameters of researched objects.

This report may be used **for regression analysis**. You may use Malmquist index value as a dependent variable and other data as independent variables. You may use KonSi-Stepwise Regression Analysis Software to research relationships between parameters contained in the report. The contents of this report are used as source data for regression analysis.

This report is generated as a .csv file which you may study using Microsoft Excel. The contents of this report are shown on Figure 10 - Figure 11.

Figure 10 Rpt4_DataForRegression. Report with joined data on Malmquist index and source object parameters displayed as an Excel table

The screenshot shows a Notepad window with the file 'Rpt4_DataForRegression.csv'. The content is a large CSV file with multiple columns. The first column lists DMUs (Data Making Units) such as 'DMU1_Jan12_Feb12', 'DMU2_Jan12_Feb12', etc. The subsequent columns contain numerical values representing input and output parameters for each DMU across different time periods (Jan12, Feb12, Mar12). The data is organized in a structured manner, with each row representing a specific DMU and its corresponding parameter values.

Figure 11 Rpt4_DataForRegression. Report with joined data on Malmquist index and source object parameters viewed in Notepad

3.5 Rpt5. Terms and names used in reports

This report has name as **Rpt5_DataForPivotTable**. This report contains data about Malmquist index, its components, DEA efficiencies and object parameters. In this report, time periods information is displayed separately from object names column so that this report can be used for creating a pivot table using Microsoft Excel for your research paper.

This report is generated as a .csv file which you may study using Microsoft Excel. The contents of this report are shown on Figure 12 - Figure 13.

User's Guide for DEA Research

Diagram illustrating the structure of the Rpt5_DataForPivotTable report, showing the flow from Base time moment to Analyzed time moment, and the calculation of DEA efficiencies used during Malmquist index calculation.

Base time moment → Analyzed time moment → Malmquist index value → Malmquist index components → DEA efficiencies used during Malmquist index calculation → Source parameters in analyzed time moment → Source parameters in base time moment

Description of the first object → (points to row 2)

Time names in lexicographical order → (points to column A)

Description of object parameter values in each time moment → (points to row 2)

Figure 14 Example of source data meeting all requirements

The source data should meet the following requirements:

- The first row (parameter names row) should contain names of parameters describing researched object system;
- The first column (the DMU names column) should contain names of researched objects;
- The rest table cells should contain non-zero numerical data about parameter values of researched objects. The data should correspond to the objects enumeration order in the DMU names column and parameters enumeration order in the parameter names row;
- Each table row should store data about **one** object (unit) in **one** time moment. The pair "time moment name and object name" is defined as a data item. This pair should be unique;

- For each object, data should be provided for **all** considered time periods. The time period is determined by two moments as time interval. The first time moment is called "a base moment" (the starting point of time interval). The second time moment is called "analyzed moment" (the end point of time interval);
- Name of each data item should contain the name of the time moment (the starting point OR the end point) to which the object data are related. The time moment name should stand before the object name and be separated from it with a special symbol (underscore symbol ('_') by default). An example of a proper data item name is "sep2013_DMU1" where sep2013 is time moment name and DMU1 is analyzed object name.
- To avoid errors connected to bad recognition of time moment names or object names, neither time moment names nor object names should contain the underscore symbol ('_');

Attention! The example "sep_2013_DMU1" will cause error in object name recognition because the term "sep_2013" contains underscore symbol ('_'). Correct data item name is "sep2013_DMU1".

- The data should be sorted according to the following rules:
 - Data about the first object in all time moments should come first in source data table. After the first object, the data about the second object should be provided in a similar way etc.
 - The names of time moments should be enumerated according to their lexicographical order in terms of their names semantics (i.e. January before February, Monday before Tuesday etc.). The time moment names order should be correctly specified at least for the first object being researched.
 - The description of the first object is a template for correct recognition of other objects.

If your source data do not meet these requirements, this may lead to errors while importing data using Importer or conducting their analysis using Malmquist Index Software.

The dataset meeting all the data requirements is shown on Figure 1. In this example, the data have been provided for 4 objects (Dmu1, Dmu2, Dmu3, Dmu4) which change their parameters within 6 time moments (Jan12, Feb12, Mar12, Jan13, Feb13 and Mar13). Parameter values specified for object Dmu1 related to time period Jan12 are provided in the table row corresponding to the data item "Jan12_Dmu1".

5 SOURCE DATA PREPARATION

The KonSi - Malmquist Index Software program requires that the source data are prepared as an .xml file generated in the Importer utility.

To prepare your data for analysis in KonSi - Malmquist Index Software, do the following steps:

1. Make sure that your source data meet all requirements. For source data requirements, see **Section 4** or Figure 14.
2. Save the data as a .csv file. On Figure 15, you can see how to properly save your data in this format using Microsoft Excel.
3. Import the saved data file to .xml format using the Importer utility.

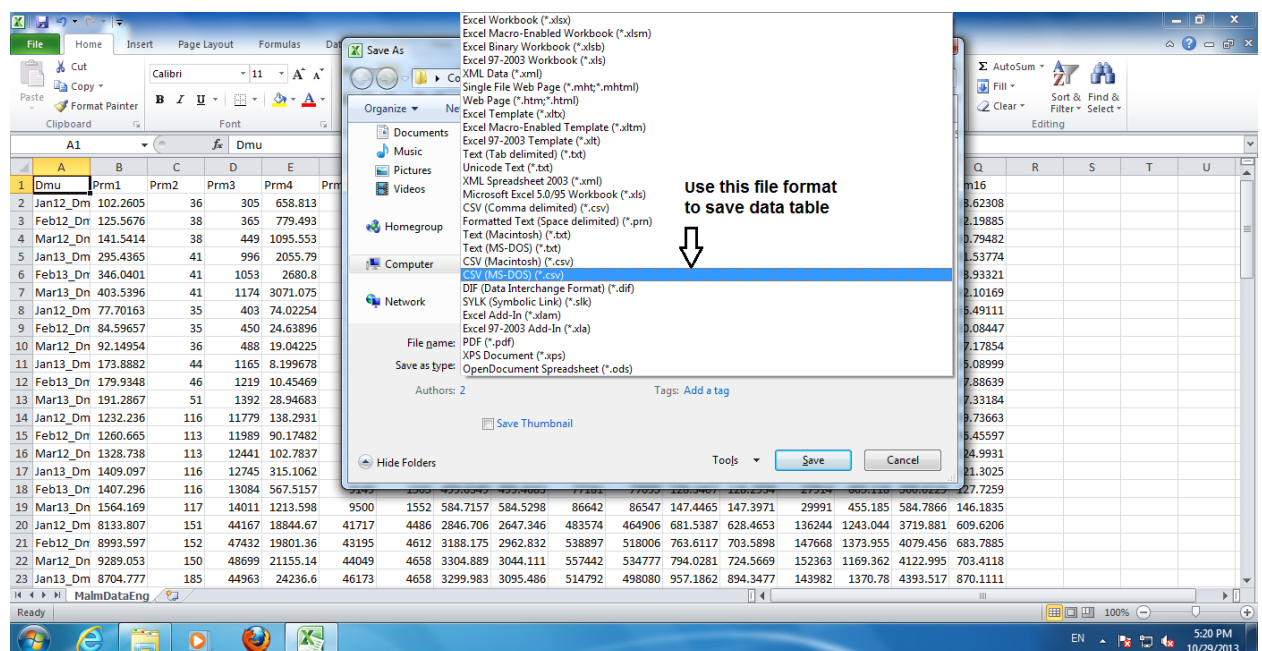

Figure 15 Example of saving source data to .csv file using Microsoft Excel

6 IMPORTER. IMPORTING SOURCE DATA

To import the data in Malmquist Index Software execute following actions.

Step 1. To launch the Importer utility, click Start, click All Programs, click KonSi – Malmquist Index Software and then click 1_Import Source Data to xml file. (Figure 16)

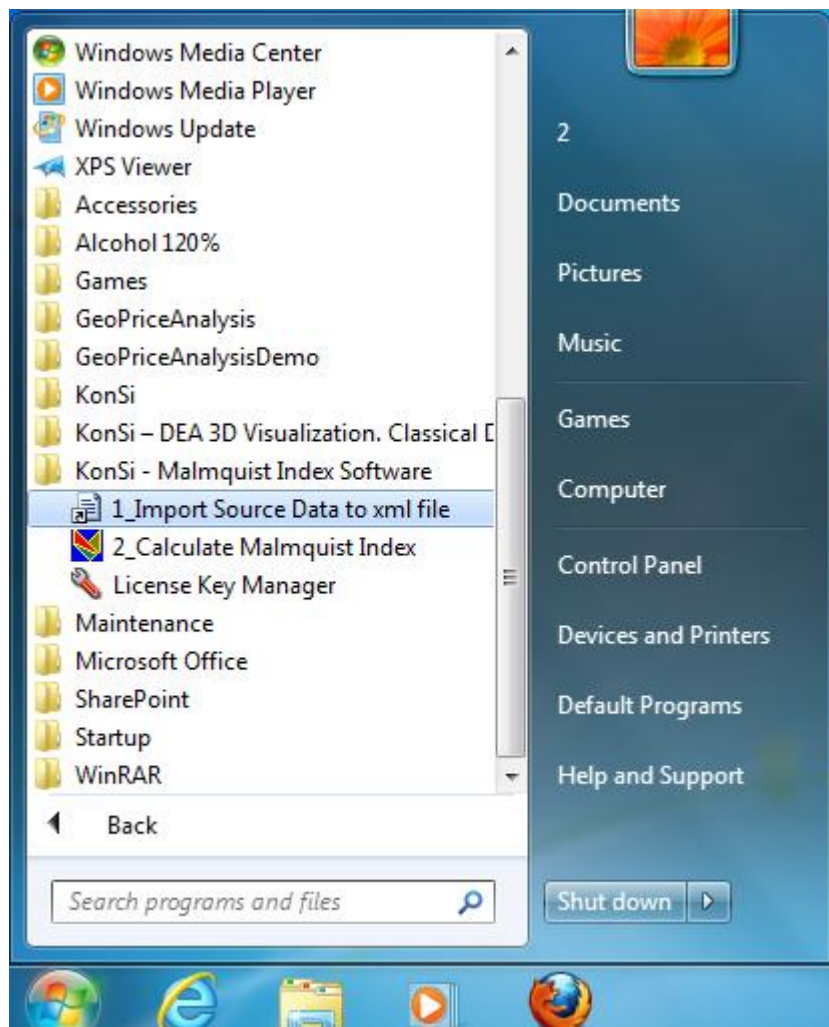

Figure 16 Launching Importer utility from the Start menu

Step 2. In the Importer utility window, click **Run Import** in the main menu or click **Import** button in the main window (Figure 17).

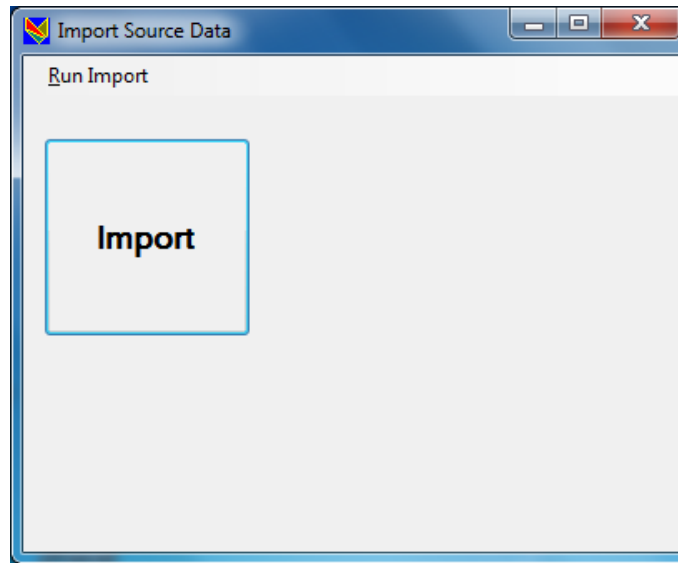

Figure 17 Launching data import wizard in the Importer utility

Step 3. In the **Import Source Data** window, click **Open** button. In the **Open** dialog box, select your source data prepared as .csv file and click **Open** (Figure 18). The preparation of source data as a .csv file is described in section 5.

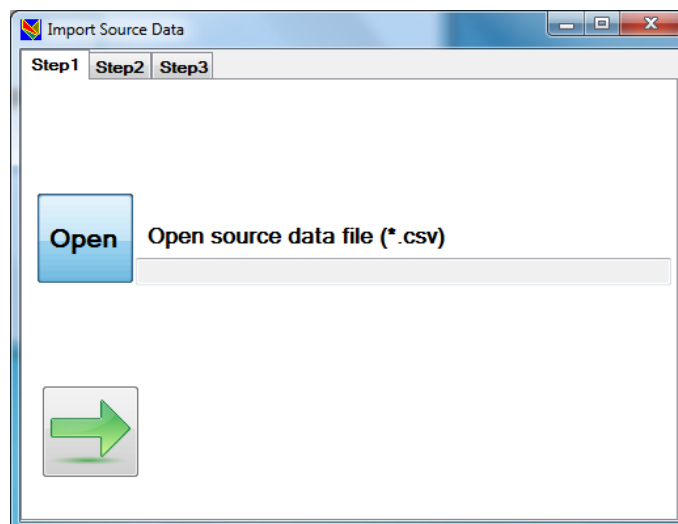

Figure 18 Opening a .csv source data file at step 1 of the data import process

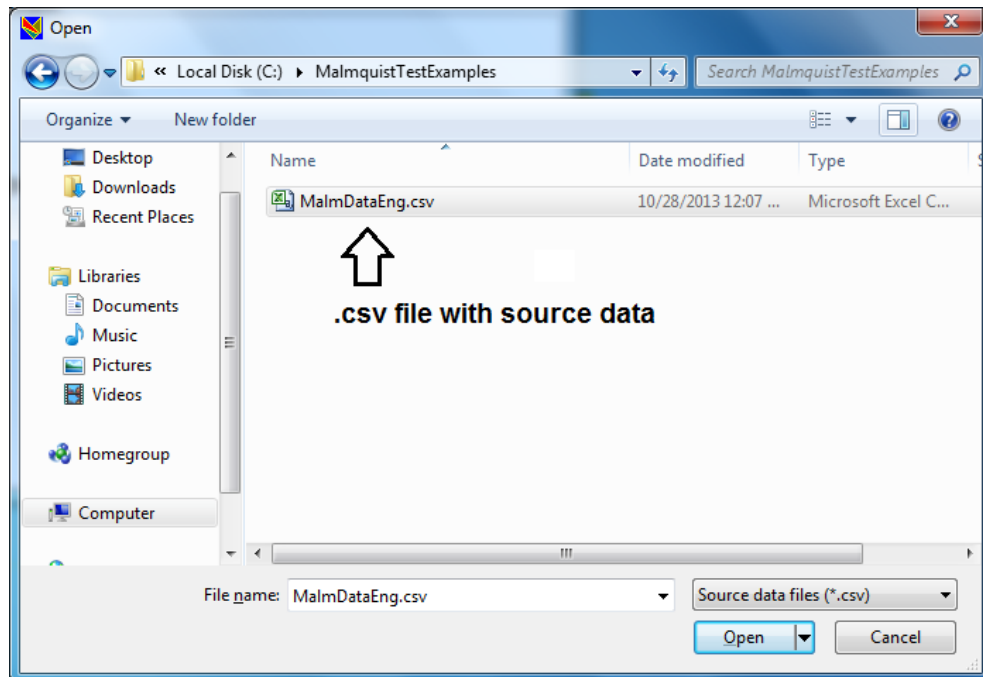

Figure 19 Selecting a source data file at step 1 of the data import process

Step 4. In the Import Source Data window, click the **Next** button (Right Arrow on Figure 18).

Step 5. Indicate where you would like to save your generated .xml file. You may do this in two ways:

If you want to save the generated .xml file in the same folder as the one containing your .csv file (by default), click Next (Right Arrow on Figure 20) to finish the process of generating the .xml file.

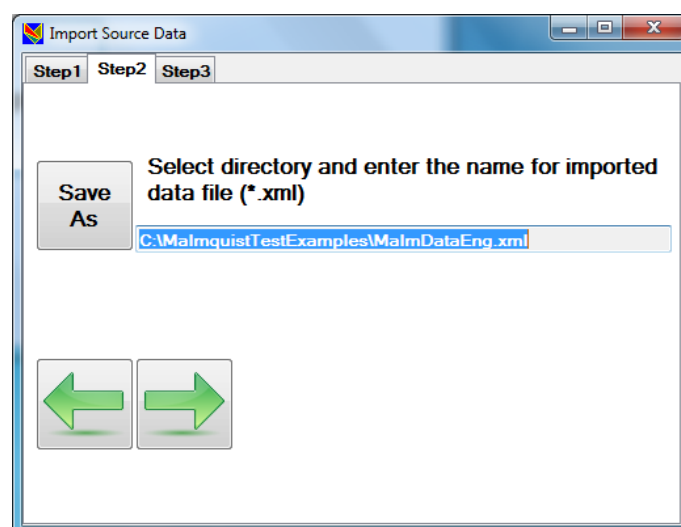

Figure 20 Saving generated .xml file under default name

If you want to save the generated .xml file in another folder and/or under another name, click **Save As**. In the Save As dialog box, define a path to your generated .xml file and enter its name in the File name box (Figure 21). Click Save and then click Next.

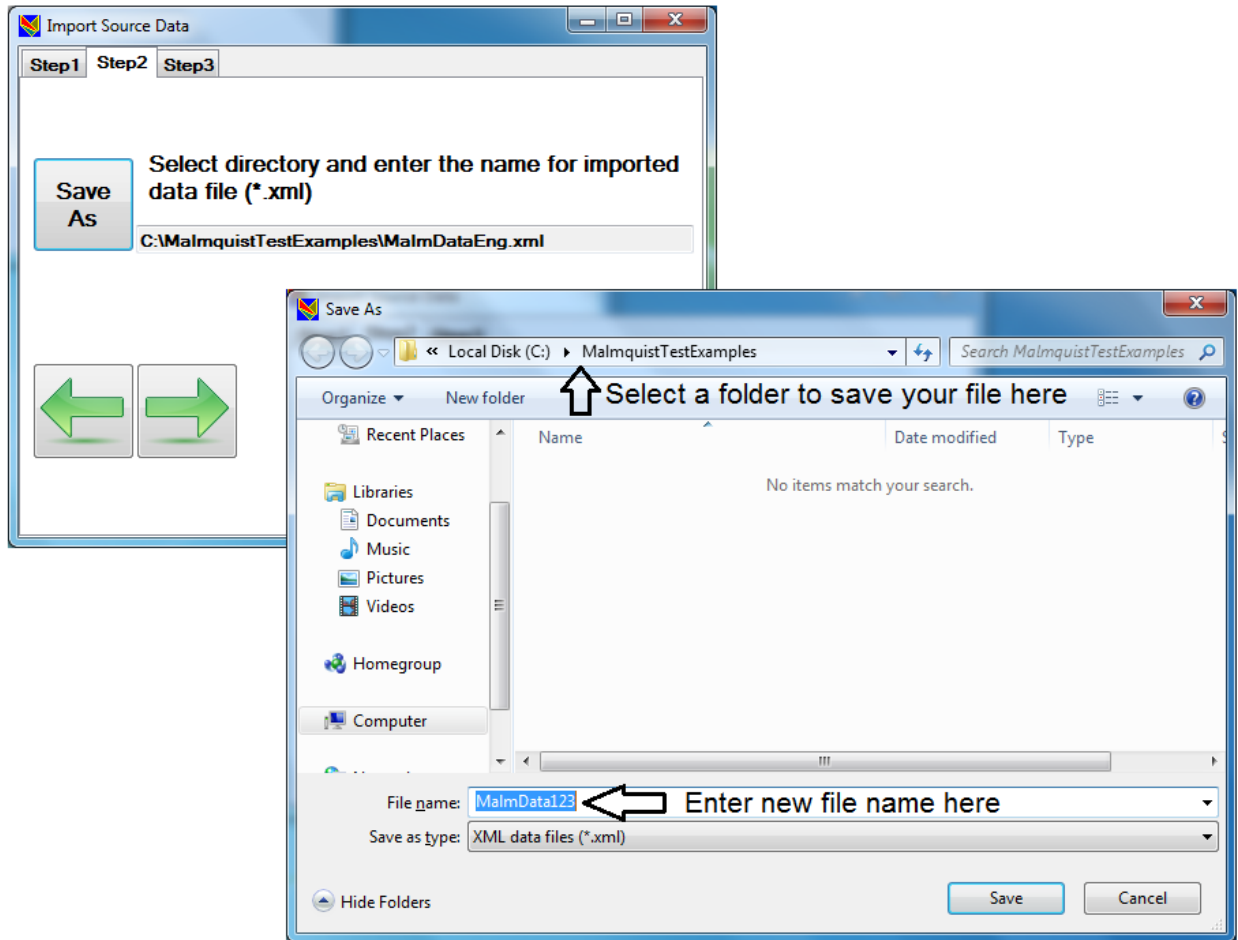

Figure 21 Saving generated .xml file under another name

Step 5. Finish import

If the .xml file is successfully saved, you see the window with the message about successful data import as shown on Figure 22. In this case, click **Finish** button with “smiling face”.

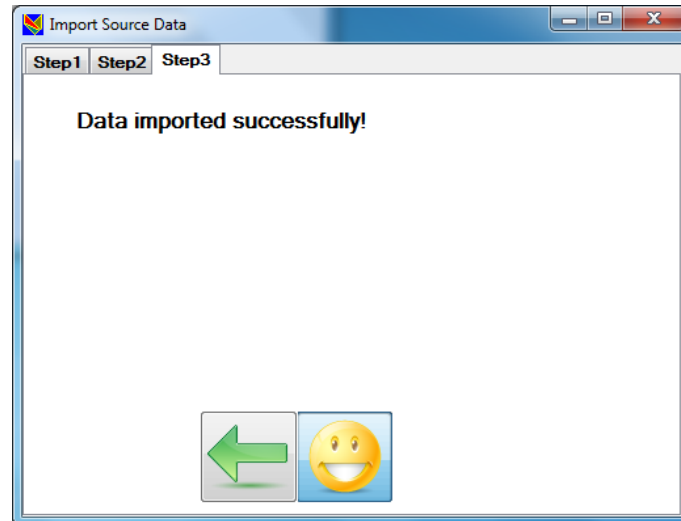

Figure 22 Message given in case of successful .xml data file generation

If the process fails, the window will contain an error message as shown on Figure 23. If you see an error message similar to the one shown on Figure 23, click the Close button ("angry face"). Close the program and correct your source data so that they meet the requirements described in Source Data Requirements section. After that, execute steps 1 – 5 again. For possible errors appearing during the import process, see Appendix "Messages Produced by .csv File Importer".

Figure 23 Error message given in case of failed .xml file generation

7 MALMQUIST INDEX CALCULATION

In this section you will learn how to process source data by using our software to calculate Malmquist Index values.

Once you create the .xml data file, you may process it using Malmquist Index Calculator. To use Malmquist Index Calculator, do the following steps:

Step 1. To launch Malmquist Index Calculator, click Start, click All Programs, click KonSi – Malmquist Index Software and then click 2_Calculate Malmquist Index (Figure 24).

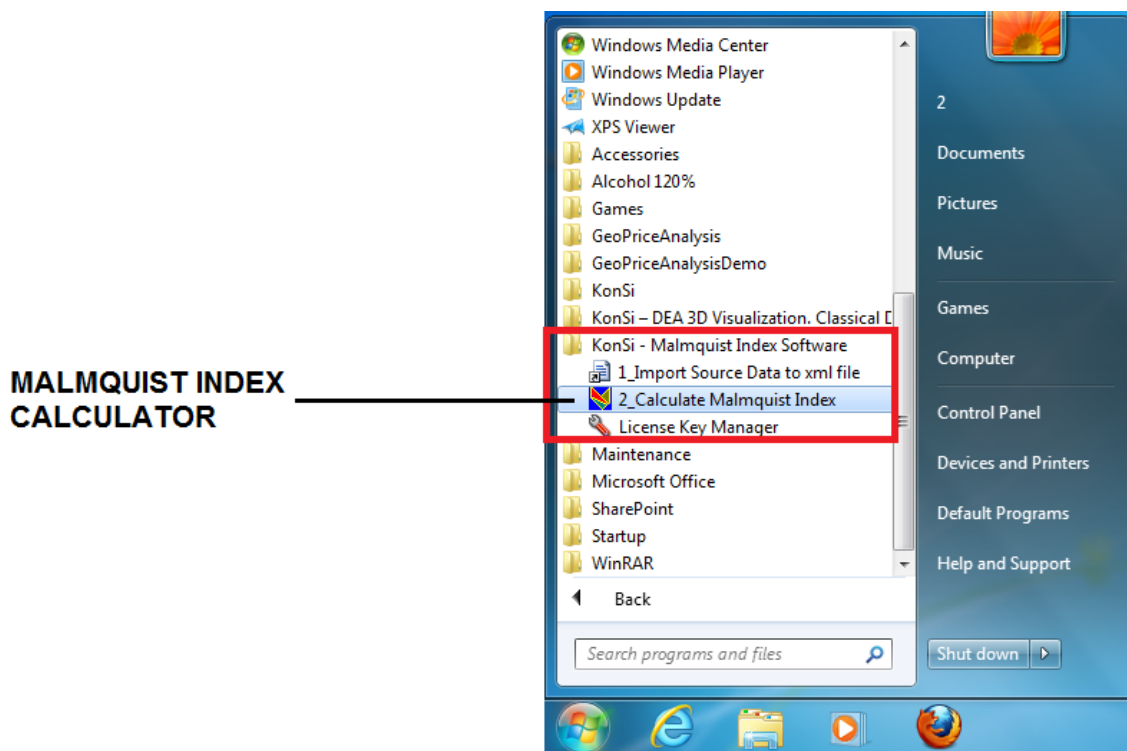

Figure 24 Launching Malmquist Index Calculator from the Start menu

Step 2. To open your .xml data file using KonSi – Malmquist Index Software, do the following steps:

1. In the main program window, click File in the menu bar. On
2. On the File menu, click Open.

3. In the Open dialog box, select your .xml data file and click Open on Figure 25. . Once you open the .xml data file, all menus in the menu bar will be enabled as shown on Figure 26.

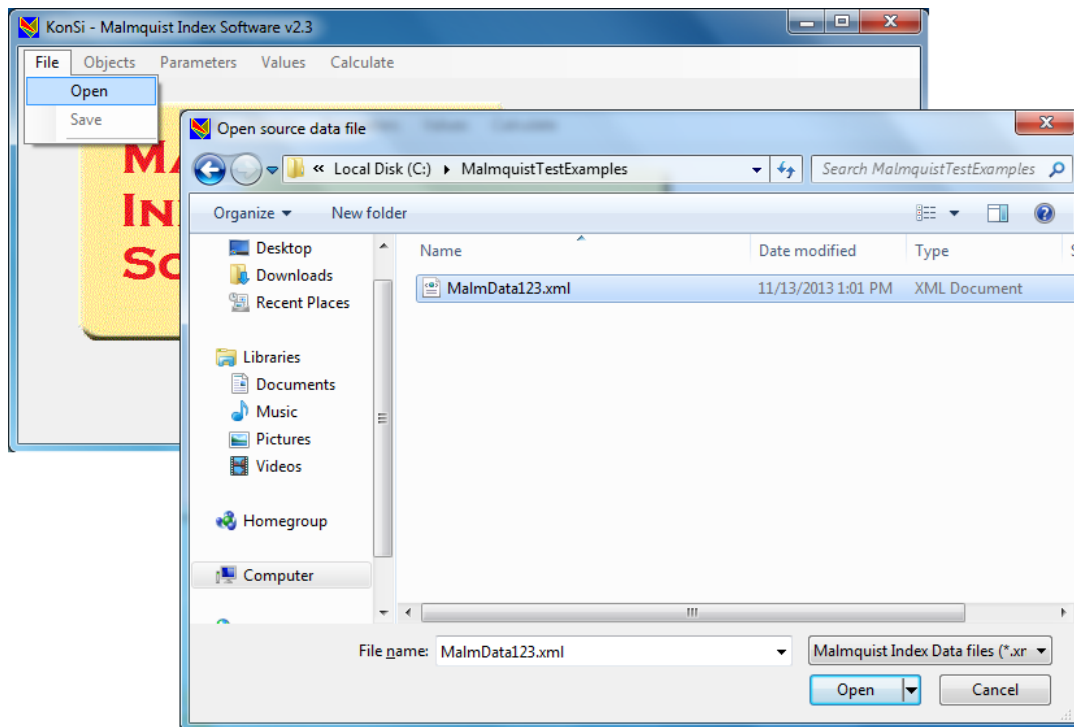

Figure 25 Opening an .xml data file using the Open command

Figure 26 Main window of KonSi – Malmquist Index Software when the source data file is opened

Step 3. If you need to define data items for which the calculations should be performed, click Objects menu in the menu bar. In the Model Objects window, select necessary data items. To select a data item for calculation, select the check box next to the data item name. Remember that your data should meet all source data requirements described in Section 4.

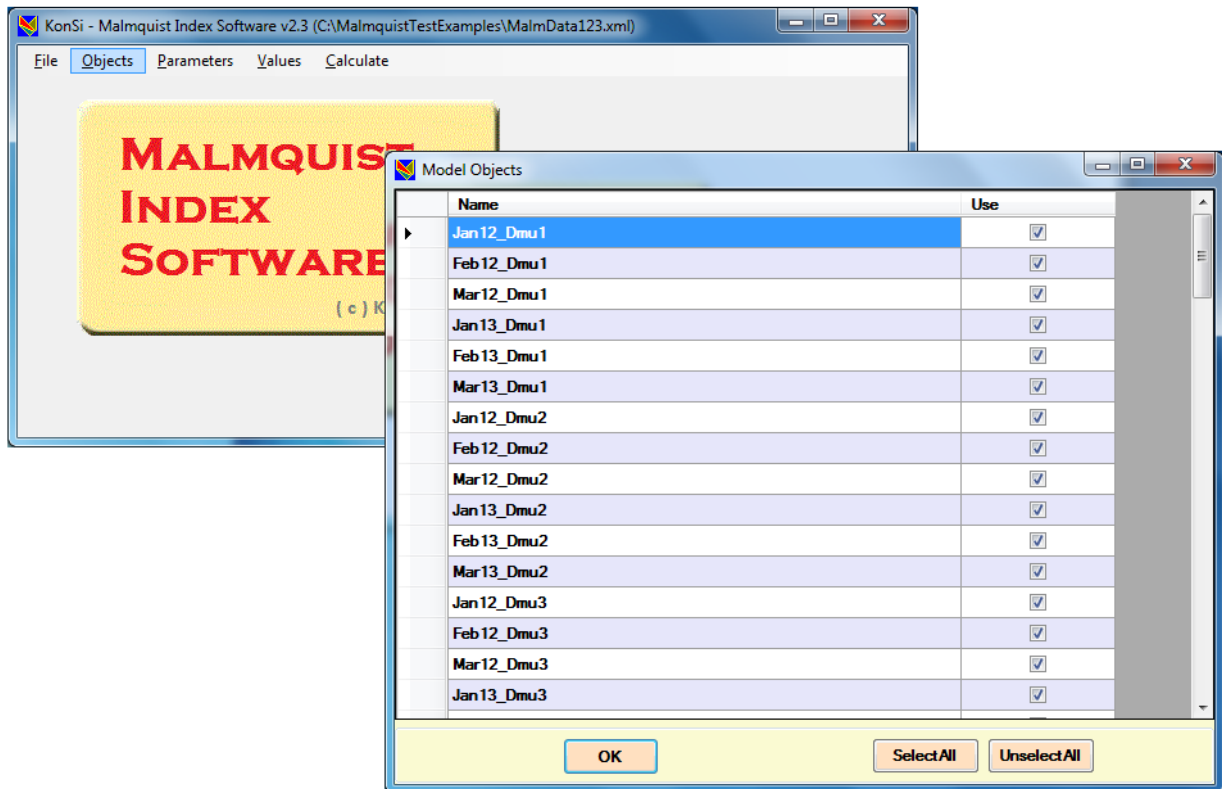

Figure 27 Select researched units

Step 4. Click Parameters in the menu bar to adjust settings of parameters which you would like to use in DEA models (Figure 28). To adjust parameter settings, do the following steps:

1. Indicate what parameters should be used during the calculation. By default, all parameters are used. To include a parameter, select the "Use Parameter" check box in the table row containing parameter name. To exclude a parameter, clear the "Use Parameter" check box in the parameters table row containing the parameter name.
2. Indicate what parameters should be considered as outputs and what ones should be considered as inputs. By default, all parameters are considered as outputs. You should have at least one input parameter. To indicate that a specific parameter should be considered as an input, clear the check box in the "Select as Output" column in the parameters table row containing the parameter name. To indicate that

the parameter is an output, select the corresponding check box in the "Select as Output" column.

3. Indicate what parameters should be considered as controlled, i.e. what parameters cannot be considered as changeable during DEA efficiency calculations. These controlled parameters have slacks. To select a parameter as controlled, select the check box in the "Select as Controlled" column next to the parameter name. If a parameter should be considered as uncontrolled, clear the corresponding check box in the "Select as Controlled" column.

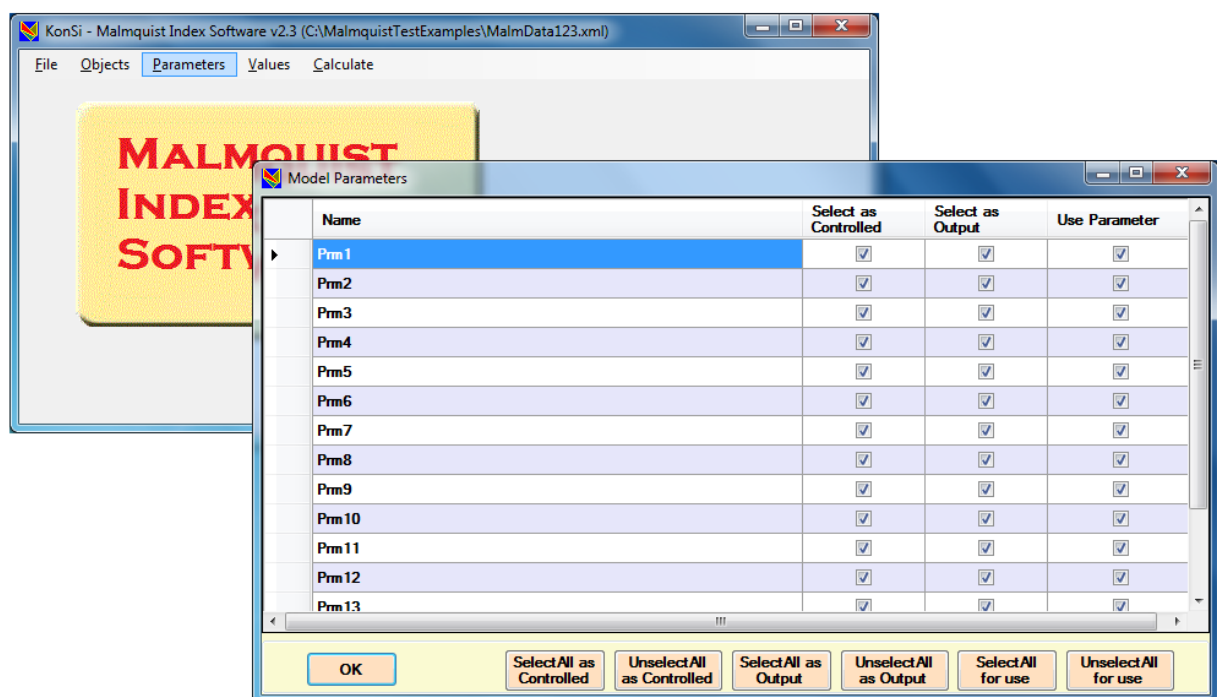

Figure 28 Define DEA model parameters for calculation of Malmquist Index

An example of parameter settings adjustment is shown on Figure 29. In this example, only 3 parameters are used in DEA models (Prm1, Prm8 and Prm14). The parameter Prm8 is defined as an output and the other two parameters (Prm1 and Prm14) are defined as inputs. All parameters are considered as controlled.

Step 5. Specify the settings of Malmquist index calculation.

In the Malmquist Index Calculation window (Figure 30), specify the following settings of Malmquist index calculation:

- Type of DEA tasks solved while calculating Malmquist index and its components (input or output oriented tasks);
- Method of Malmquist index calculation (fixed base, adjacent base, seasonal calculation).

For description of methods used by the program, see **Methods of Malmquist index calculation used by KonSi – Malmquist Index Software.**

The screenshot shows a window titled "Model Parameters" with a table containing 16 rows, each representing a parameter (Pm1 to Pm16). The table has four columns: "Name", "Select as Controlled", "Select as Output", and "Use Parameter". Each row has checkboxes in the last three columns. The "Select as Output" checkbox for Pm8 is checked, and the row is highlighted in blue. Below the table are several buttons: "OK", "Select All as Controlled", "Unselect All as Controlled", "Select All as Output", "Unselect All as Output", "Select All for use", and "Unselect All for use".

Name	Select as Controlled	Select as Output	Use Parameter
Pm1	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Pm2	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm3	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm4	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm5	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm6	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm7	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm8	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>	<input checked="" type="checkbox"/>
Pm9	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm10	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm11	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm12	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm13	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm14	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input checked="" type="checkbox"/>
Pm15	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>
Pm16	<input checked="" type="checkbox"/>	<input type="checkbox"/>	<input type="checkbox"/>

Figure 29 An example of parameter settings adjustment

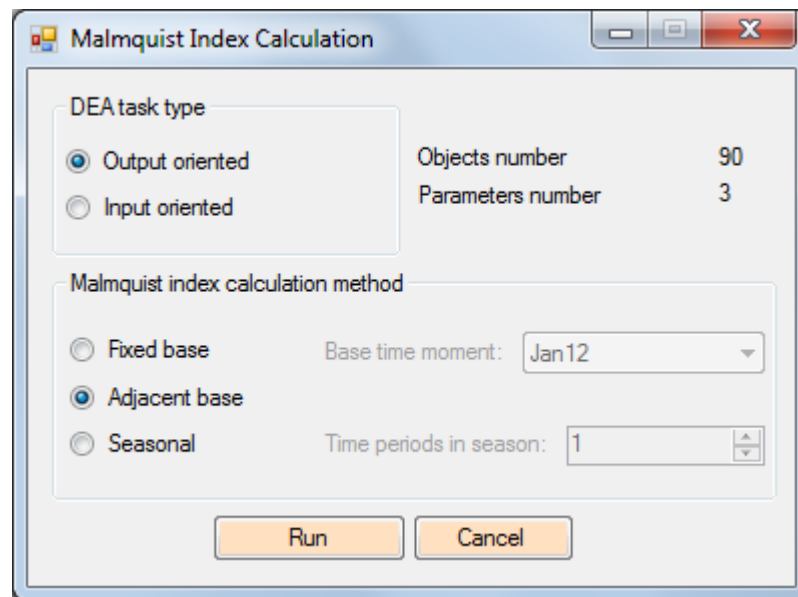

Figure 30 Malmquist Index Calculation window

If you want to use fixed-base method, click **Fixed base** and then select a moment you want to use as a base moment in the **Base time moment** box (Figure 31).

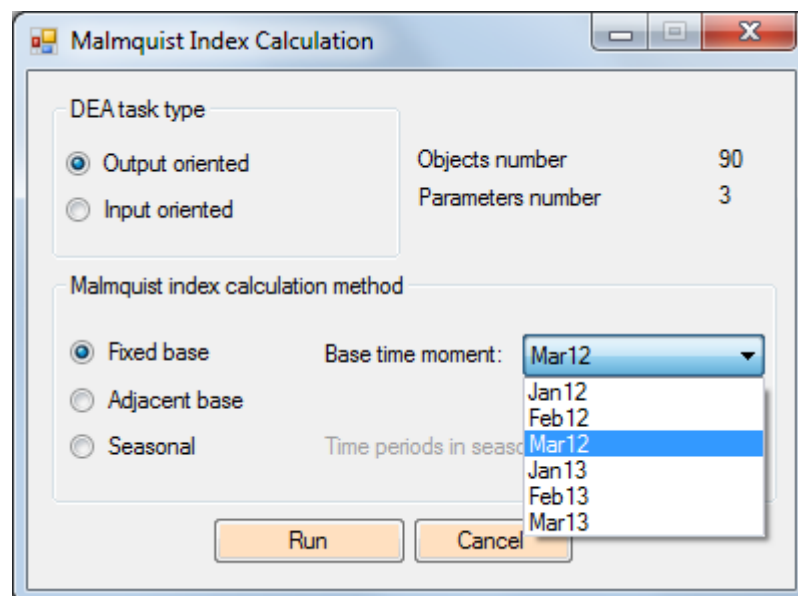

Figure 31 Selecting base time moment when using fixed-base calculation method

If you want to use adjacent-base method, click **Adjacent base**, which is set as a calculation method by default.

If you want to use seasonal calculation method, click **Seasonal** and set a value for time periods quantity in a season in the **Time periods in season** box (Figure 32).

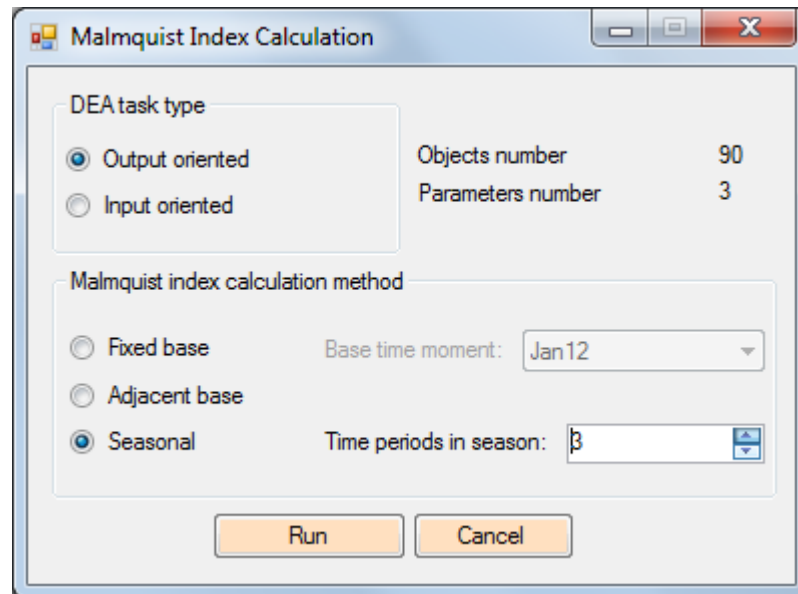

Figure 32 Selecting time periods quantity in a season when using seasonal calculation method

Step 6. Calculate Malmquist Index values. Click **Run** in the **Malmquist Index Calculation** window. After that you must save calculated reports. In the **Browse For Folder** dialog box, select a folder where you would like to save reports generated by the program and then click **OK** (Figure 33).

Figure 33 Select a folder where you would like to save reports

WARNING: When you generate new reports, check that all reports generated before are closed. If any of the reports generated before is already opened, the program will terminate and you will receive an error message (Figure 34).

Figure 34 Error message given when any report generated before is opened

The results are saved in five .csv report files. For the description of reports generated, see **Reports generated by KonSi – Malmquist Index Software**.

8 HOW TO STUDY DEMO EXAMPLE

The data of demo example are located in the **Example** folder, which is contained in the downloaded software archive.

Files and subfolders contained in the Example folder are shown on the Figure 35

Figure 35 Folder with demo example

Source data

To study source data example, select one of the following two folders:

- ImportedData DecimalSign AS Commas
- ImportedData DecimalSign AS Points

Files in these two folders differ only by the decimal sign used in numbers (comma or point). If you use American format settings, select the folder with data using point as a decimal sign (the "ImportedData DecimalSign AS Points" folder).

The selected folder contains two files (Figure 36). The .xls file contains source data prepared for importing. Before starting the importing process, these data should be saved as a .csv file. The .csv file is used by the Importer utility to create an .xml file for calculating Malmquist Index.

Figure 36 Examples of source data files

Studying Importer utility

To study the Importer utility, launch this utility and select the .csv file containing source data.

The Importer utility creates an .xml file for calculating Malmquist index. An example of this .xml file is stored in the **Example** folder (file named **MalmquistIndexCalculationData.xml**).

Studying Malmquist index calculation

To study the utility of Malmquist Index calculation, launch Malmquist Index Calculator and open file **MalmquistIndexCalculationData.xml**. After that, execute commands of this utility as described in Section 7.

Studying Malmquist index reports

To study the reports created by Malmquist Index Calculator, open the **MalmquistIndexReports** folder (Figure 37) . Description of these reports is given in Section 3.

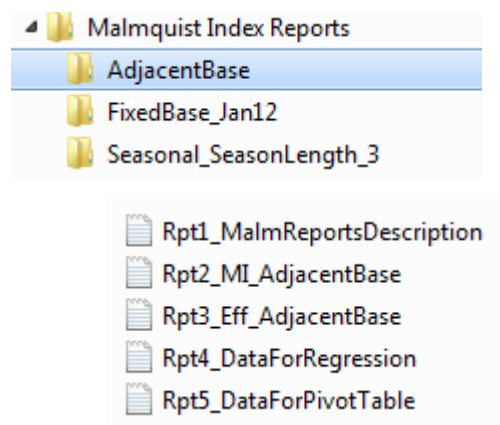

Figure 37 Folder with reports on Malmquist Index (for example, created using Adjacent Base Malmquist Index Method)

9 APPENDIX: MESSAGES PRODUCED BY CSV FILE IMPORTER

- **Data Import Errors**

«Column 'Caption' is constrained to be unique. Value '...' is already present..»

Reason:

Two or more data items in your source data have equal names.

- Each table row should store data about **one** object in **one** time moment. The pair "time moment name and object name" is defined as a data item. This pair should be unique;

Possible solution:

Check whether there are data items with equal names in your source data. Control that **one** object is in **one** time moment. Try to correct data item names so that they become unique.

«Column 'VarName' is constrained to be unique. Value '...' is already present..»

Reason:

Two or more parameters in your source data have equal names.

Possible solution:

Check whether there are parameters with equal names in your source data. Try to correct their names so that they become unique.

«Value was either too large or too small for a Double. Couldn't store <...> in Val Column. Expected type is Double..»

Reason:

Some of your objects have parameter values larger or smaller than possible.

Possible solution:

Check parameter values of your model objects. They all should belong to the range $[-1.79769 * (10^{308}), 1.79769 * (10^{308})]$.

«Cannot set column 'VarName'. The value violates the MaxLength limit of this column..»

Reason:

Some of parameters in your model have too long names.

Possible solution:

Check your model parameters given in your source data. The name length of a parameter should be less than or equal to 255 symbols. Try to shorten those names which have length more than 255 symbols. For example, you may use abbreviations.

«Cannot set column 'Caption'. The value violates the MaxLength limit of this column..»

Reason:

Some of your data items have too long names.

Possible solution:

Check your source data items with too long names. The name length of a data item should be less than or equal to 255 symbols. Try to shorten those names which have length more than 255 symbols. For example, you may use abbreviations.

«Input string was not in a correct format. Couldn't store <> in Val Column. Expected type is Double..»

Reason:

Values are not set for some parameters of your model. Values should be set for all parameters of each object.

Possible solution:

Check whether there are empty parameter values in your source data table. If they are supposed to be equal to zero, replace them to very small value , for example, 0.0001.

«Input string was not in a correct format. Couldn't store <...> in Val Column. Expected type is Double..»

Reason:

There are either infeasible symbols in your source data table, or some numbers have two or more fractional separators (decimal points).

Possible solution:

Check your source data table for infeasible symbols in the numeric data region. The only feasible symbols for typing in parameter values are digits and the fractional separator („." by default).

REMARK:

If it is necessary for you that some parameters or objects of your model have names including a comma, which is the separator of table columns in CSV files by default, then you should enter such names in quotation marks (eg. „ "Sales, output 2" "). Otherwise, the data after the comma will be recognized by the program as belonging to another column and you may get an error "Input string was not in a correct format."

NOTE: You do not have to use quotation marks if you use Excel for editing CSV files.

«Error while opening CSV file. Object reference not set to an instance of an object..»

Reason:

There could be a backslash symbol ("\\") in your source data table.

Possible solution:

- Check your source data table for a backslash symbol ("\\"). If you find it, delete it and try again.
